Abstract—*Spirulina platensis* and other microalgae are now being considered in the different fields of research. It is due to the latter's endless potential, especially that it has high protein content. That is why, a stable demand of microalga production is now necessary.

To achieve a high-protein spirulina, its cultivation requires monitoring and maintenance of the bio-environmental factors affecting its growth. This is in order to provide a stable and efficient production of microalgae. Meanwhile, laboratories that culture spirulina determine its cell count/cell density through manually counting the cells under a microscope – a tedious work. This establishes the need to construct a device that cultivates spirulina with maintaining and cell counting capabilities. Thus, the proponents developed a culturing device that has three main systems. The first system is tasked to monitor and to correct the bio-environmental parameters, such as the pH level, temperature, and light. The second system on the other hand speaks of the cell counting system through ImageJ's Morphological Image Processing. This system verifies the cell density and growth through counting the filaments of the spirulina. Lastly, is through a corresponding android application that displays real-time values of the culture's parameter. Results from the experimental proper show that the device was able to stabilize its parameters. Furthermore, red LEDs exhibited 28.43% higher approximate cell count than red blue LEDs.

Keywords—*Spirulina platensis*, ImageJ, image processing, closed algal cultivation, parameter monitoring, Firebase

I. INTRODUCTION

Spirulina is a blue-green microalga that grows in alkaline lakes. It is highly used and is currently in great interest due to its high protein content [1]. Spirulina is now produced in large batches and is cultured in either open or closed systems. Ponds are usually used in open systems, while closed systems are in any container that has controlled parameters. Major disadvantages of open ponds are the contamination of the culture and the changing condition of the environment. Closed systems, on the other hand, has the defense for contamination. Essential parameters such as

temperature, pH level, and oxygen level can also be monitored using closed systems. Mixing is necessary for the maintenance of these parameters especially to the homogeneity of the light absorption of the culture. Also, mixing ensures that the nutrients are scattered all throughout the culture. As for the temperature, it is maintained by submerging the container to a pool of water, by using heat exchanger, or spraying the outside of the container with water. Light is the most important parameter in culturing spirulina [2]. Since *Spirulina platensis* is under the phylum cyanobacteria, it is photoautotrophic. It utilizes the process photosynthesis in making own food [3].

Spirulina platensis cell counting is usually done in laboratories through a 'cell counting chamber' called Hemocytometer. It is simple, direct, and cheap but it is also laborious and time consuming because of its unusual cell shape and cell suspension. Making this method susceptible for human errors [4].

The amount of the spirulina obtained after the farming is important. It is desired to have great amount of spirulina produced in one cycle of culturing. It is settled that the counting and the detection of *Spirulina* cells are extremely tedious to be done manually. From these, the implementation of image processing is considered since image processing as a means for cell counting proved its effectivity in numerous studies and one of the main applications of digital image processing is estimating the total number of a specific object in each image [5].

The study aims to build a device with maintenance and correcting system; to create a vision system that captures images of samples then counting the cells; and to create an Android application for the real-time monitoring of the parameters using IoT platform.

A device that counts the filaments is a great help for the spirulina farmers to save time and to have accurate cell counts is what the research is aimed at.

II. RELATED STUDIES

A study by Bautista et al. [6] also measured, monitored, and corrected parameters essential in culturing *Spirulina platensis*. Their system also has a vision system that comprises of a camera and a sampling cube. Artificial neural network was trained and then used as an algorithm in analyzing the algal concentration.

The detection and correction system were adapted in this past study [6], except for the dissolve oxygen parameter, vision system and the algorithm that were used in their image processing. Thus, said vision system was improved and the algorithm was also changed. Additional one difference between the past study and this one is the visualization of data. This study made use of an Android application that displays the data and their graphical representation for each parameter.

In [7], this study incorporates temperature, UV intensity, and water turbidity sensors, microcontroller, and cloud services for their spirulina culturing system. It also made use of the IoT platform and the Android app to acquire, visualize, and monitor data gathered within the smart micro farm. This study used ThingSpeak as database and MIT Appinventor to create their application.

This study [7] focused on the implementation of IoT and Android application. Parameters were just measured, not corrected.

A study by Fei Jia [8] is an optical sensor unit that is responsible for measuring cell concentration and changes of the physiological status in the culturing system in real-time. This optical sensor was made up of three laser diodes different wavelengths. This study also developed a graphical user interface (GUI) in their control station. Environmental conditions, such as temperature, were controlled using this control station. The real-time data sent to the control station using Ethernet.

The optical sensor unit in [8] utilizes flow cytometry, so air pump was used to acquire culture to pass through the unit. Culture passing through the pump might not get enough light and it might get stuck on the surface of the tube, affecting the flow rate. Their GUI and control system are not portable because they are attached to the system.

A study by Niangoran et al. [9] concludes that using red light in the culture produced more biomass than any other color of light.

To obtain a high protein alga, parameters such as pH level, temperature, as well as light should be considered. Which most aforementioned study only took one or two parameters into account. Thus, this study considered monitoring these key parameters to prove that the said parameters were necessary in producing a greater growth of the microalgae. Moreover, a device that can ease the cell counting system was proposed in this study. Through an algorithm which is purposely designed for scientific image processing. This image processing technique was made with ImageJ. Furthermore, implementing the IoT concept with Firebase and Android Studio made monitoring and data

acquisition easier. This is because both is in real-time and can be done remotely.

III. METHODOLOGY

Fig. 1 shows the block diagram of the entire system. The culturing device has three main parts: the culturing system, the vision system, and the android application. The culturing system is responsible for the monitoring and maintenance of the parameters. Monitoring includes temperature and pH sensors. Data from the measured parameters will be sent to the Arduino and if the values of the parameters are out of the desired range, maintenance takes place by correcting the parameters. The Arduino opens or closes maintenance through a relay. The Arduino is also connected to the Raspberry pi which is responsible for sending data to the cloud. The Raspberry pi and cloud were also included in the android application part as well as its interface. The application displays the data from the parameters and their graphs, including the cell counted from the vision system for the real-time monitoring. Fig. 11 shows the acquired data from the cloud in graphical form. Finally, the vision system where the cell counting occurs, is fitted in a small black box where samples in petri dish are placed. After images are taken using a fixed hand-held microscope camera, the images are then processed, and cells are counted using ImageJ's morphological processes. Fig. 3 shows the functions done in the images and the counting of the filaments by the ImageJ's image processing.

Fig. 2 shows the process of maintaining the parameters. Which starts off with the sensors simultaneously reading the pH and temperature of the culture. Then, data gathered will be verified if it is in the ideal range. If the parameters, either pH or temperature were in the ideal range, current data were sustained. However, if the pH level read is higher than the ideal range, Phosphoric acid will be added to the system. If it is lower, Sodium Hydroxide will be added. Likewise, if the temperature read is higher than the ideal range, the maintenance system will run the cooling fan. And if it is lower, the maintenance system will run the heater. This process will repeat unless the ideal range is maintained.

Fig. 4 shows the top, front, side views, and the dimensions of the device. It is made from a half-inch thick plywood and the edges were finished with aluminum angle bar. The wood box is C-shaped, and the aquarium is placed in the middle. At the top part of the box, above the aquarium, is where the electronic circuits, air pump peristaltic pumps, and the power supply lie. They are fixed in a piece of acrylic so that they do not move easily. There is also a small hole that acts as a passage of wires. The back part houses the vision system and the two wash bottles. This part is for the tall components. The bottom part is a drawer. This drawer serves as a storage for the essential tools in culturing *Spirulina*, such as the syringe, the sampling dishes, and the plankton net. Moreover, Fig. 5 shows the actual device.

Furthermore, the results obtained in this study were statistically evaluated. T-Test was applied to determine the if there is a significant difference in using a different color of LED as artificial light in culturing *Spirulina platensis*.

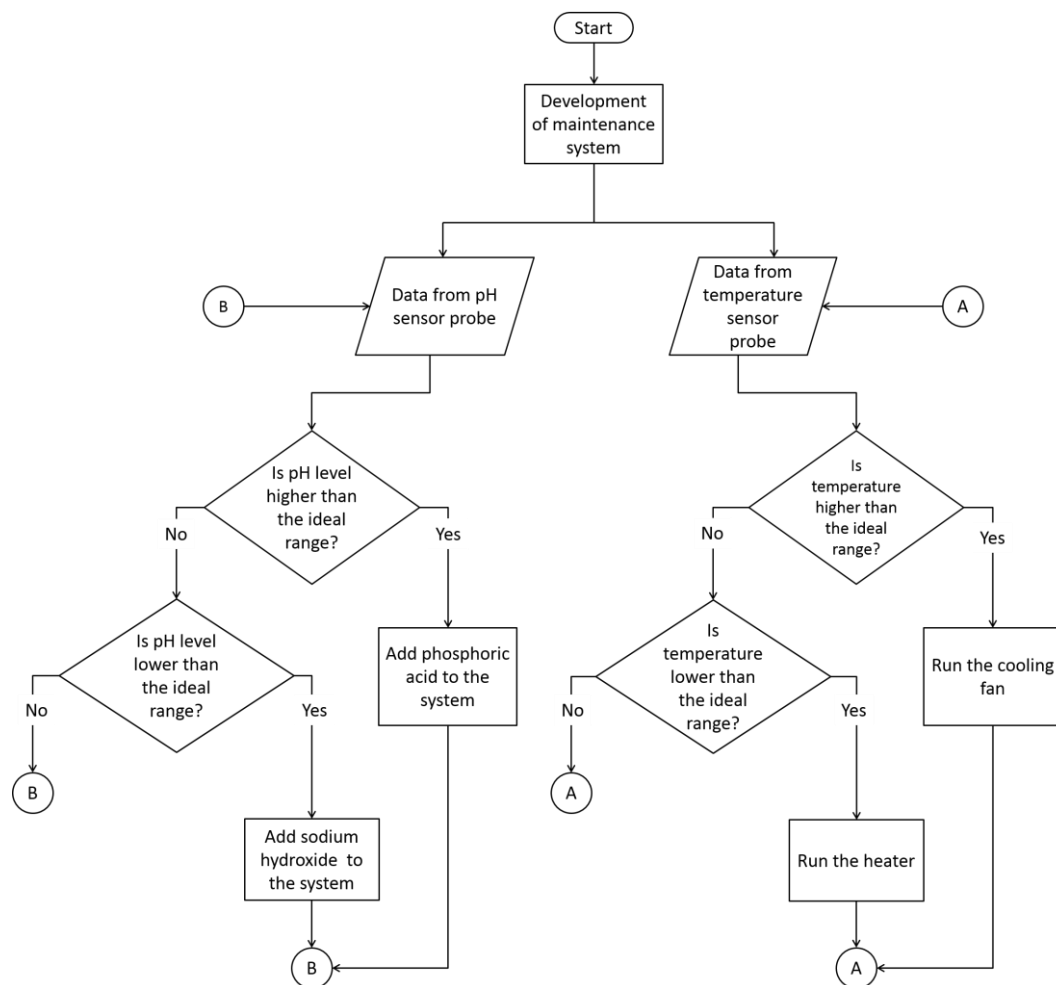

Fig. 2. Parameter Maintenance Flow Chart

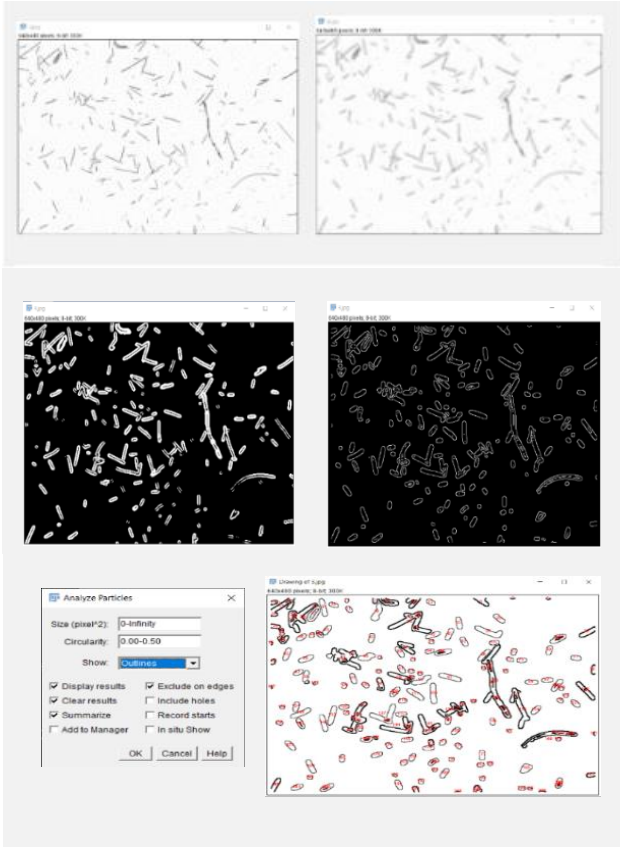

Fig. 3. ImageJ's Image Processing Steps

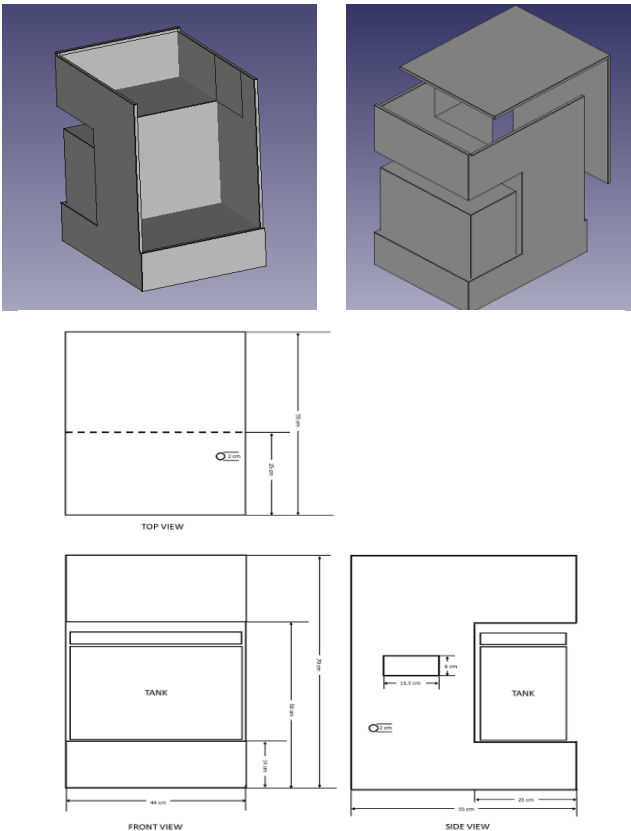

Fig. 4. The design of the system

Fig. 5. The assembled prototype

At the same time, regression analysis was utilized in order to determine the growth rate of *Spirulina platensis* under different artificial lighting treatment over time.

The exponential analysis is given as:

$$y = \alpha e^{\beta x}$$

Where:

y = Cell count
 α = equation coefficient
 β = growth rate
x = number of days past

IV. RESULTS AND DISCUSSION

The culture prepared for this study was composed of 80% SOT medium and 20% inoculum of pure *Spirulina platensis*. Three parameters were assessed for the constructed cultivation system. These are the temperature, the pH level, and the lighting. The constructed closed cultivation system underwent a 7-day test run in order to evaluate the latter's functionality. The plotted graphs below would show the measured temperature and pH level obtained from the cultivating system for 7 days.

Fig. 6 shows the obtained temperature of the microalgae during the 7-day run. The system maintained the temperature within the specified target range of 29 to 32 degree Celsius. The starting temperature of the culture was 25.5°C and it progressively reached the specified range for the parameter's maintenance optimal range. The

monitored temperature contains numerous changes but is still at the applicable set of temperature.

Fig. 7 proves that the device maintained the pH level of the culture during the test run. The culture began with a pH level of 7.28 for the reason that the water that was used for the culture was distilled. As it progresses, the culture's pH level immediately rose to the parameter's target optimal range which was between 8.5 to 9.5. Since then, the said parameter has been maintained. It also showed stability and it did not exceed the desired alkalinity for the microalgae.

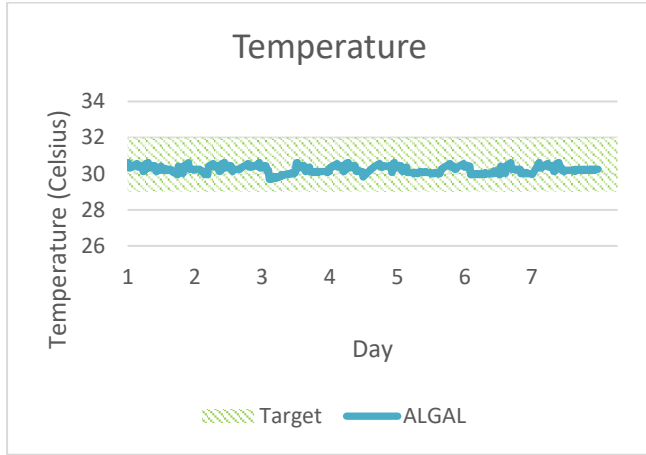

Fig. 6. Temperature of the system during the 7-day test run

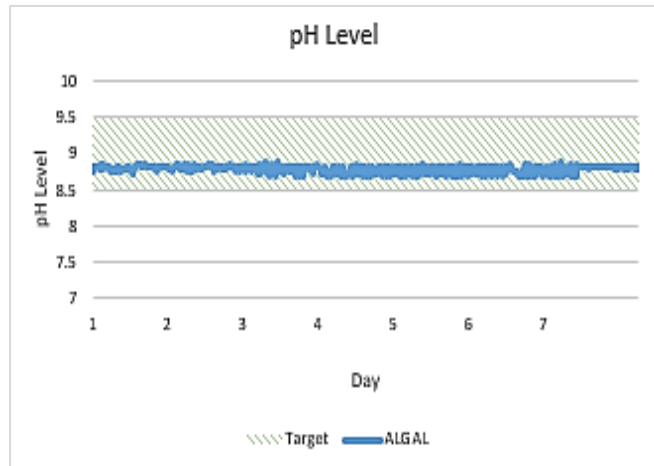

Fig 7. pH level of the system during the 7-day test run

The proposed system was compared with a previous study [6] to verify which set-up yields better growth of *Spirulina platensis* as shown in Table I. The latter has been re-enacted with the same conditions except that this experiment uses 20% of inoculum. The medium used for each culture was SOT culture media. On the other hand, the bio-environmental factors such as pH level and temperature were monitored. Meanwhile, Bautista et al. proved that the culture's DO level remained on its ideal range which was 10-25 mg per liter. Thus, this study did not monitor the DO level of the culture anymore. The cultures were also aerated to obtain homogeneity in light absorption. This study uses Red LEDs as artificial lighting whereas the past study uses a Red-blue LEDs. For the

vision system, to determine the cell count of the culture, the previous study used RGB analysis using Artificial Neural Network, while this study opted to made use of the microscopic image analysis using ImageJ. Furthermore, IoT implementation and Android application were implemented in this study, whereas the previous study did not.

TABLE I: Comparative Table between Bautista et al. and Belarmino et al

	Bautista et al.	Belarmino et al.
Inoculum	20%	20%
Culture Medium	SOT	SOT
Bio-environmental factors (pH and Temperature)	Monitored	Monitored
Dissolve Oxygen	Yes	No
Aeration	Yes	Yes
Artificial light color	Red-blue	Red
Growth rate	0.302	0.388
Vision System	RGB analysis using ANN	Microscopic image analysis using ImageJ
IoT implementation	No	Yes
Android application	No	Yes

The experimental setup also proved that Red-only LED helps increase the cell count of the *Spirulina platensis* culture compared to the previous research's Red-Blue LED setup. During its Lag phase, the Red-only displayed an early increase in growth as it progresses through the week resulting in a clear gap having an 28.43% more cell count per ml compared to Red-Blue on the seventh day. Fig. 8 shows the cell count for each light setup for 7 days.

Fig. 9 and 10, on the other hand shows the regression analyses for the two methods of artificial lighting. The growth rate of the Red LED is 0.388 while the Red-blue LED has 0.3021. The Red LED had 28.43% higher growth rate than the Red-blue LED.

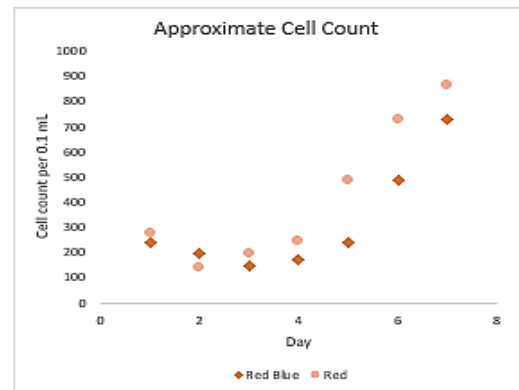

Fig. 8. Approximate cell count

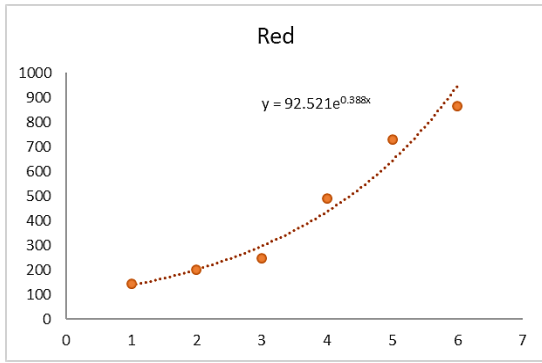

Fig. 9. Regression Analysis of *Spirulina platensis* using Red LED

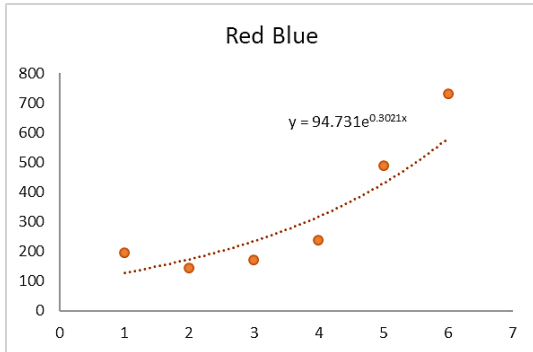

Fig. 10. Regression Analysis of *Spirulina platensis* using Red-Blue LED

Table II shows the t-test for the comparison of Red-only and Red-blue LED. The p-value 0.02 is less than the 0.05 significance level. The decision is to reject the null hypothesis, which states that the color of LED used in culturing *Spirulina* does not affect its cell count. This means that there is a significant difference between the two means.

The Android application was able to obtain the data from the pH and temperature sensors. These sensors are connected to the Arduino using Raspberry Pi. Correspondingly, the android application was programmed to fetch the upcoming data and to display the latest recorded entry the database has received per parameter. In turn, the accumulated data were presented into the developed application in graphical and numerical forms. These are shown in Fig. 11.

TABLE II: T-test for the Lighting Treatment to be used in Culturing *Spirulina*

Test Statistic:	-2.511
Pearson's r:	0.934
P-value:	0.02
Decision	Reject H_0
Interpretation	Significant

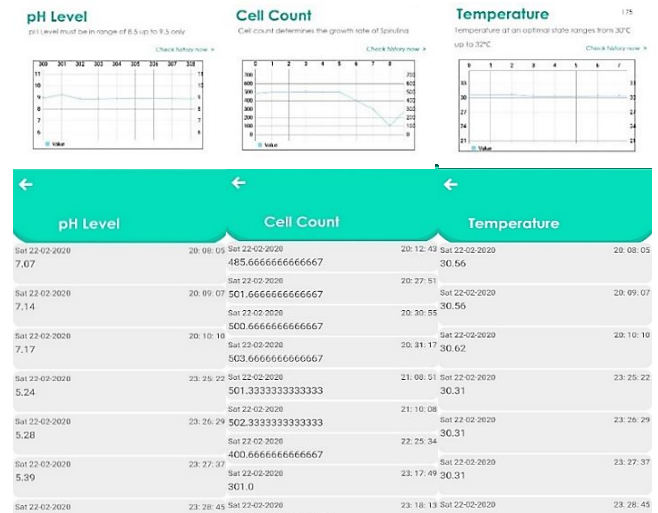

Fig. 11. Parameter Data in Graphical form in Spirulinapp

V. CONCLUSION

The maintenance system was consistent in maintaining the parameters in their respective ideal range. The culture illuminated using red LED obtained more cell count than the ones with red and blue LED. Which, in turn improved the quality of the *Spirulina* that was produced throughout the study proper. ImageJ's image processing became a good substitute in counting cells manually. Lastly, the Android application was a great help for the cultivators since it showed convenience in monitoring the necessary parameters.

For future work, this study can be applied to other aquaculture systems specially other species of microalgae which requires an optimal range of bio-environmental factors to greatly improve its growth. Furthermore, the automation of collecting samples is advised as it can limit the frequency of opening the system, reducing the contamination of the culture. Improvement or alternative for the device's camera is also advised to further improve the sample's image resolution and quality. As for the IoT implementation, data encryption and improvement of the Android application's GUI is advised for security and quality of life. Lastly, it is advised to increase the images to be assessed by the system and the timeframe in conducting the study since microalgae are species that need proficiency and precision in cultivating.

VI. ACKNOWLEDGEMENT

First, we, the Team Algal would like to thank God for guiding us through this project study, for being there since the beginning, for blessing us the wisdom and strength.

To Engr. Lean Karlo S. Tolentino, our adviser. For being with us in times we do not know what to do. For the guidance and support. For believing in us.

To Dr. Aya and Mr. Reylan Gutierrez of SEAFDEC. For sharing to us their knowledge. For answering all our

questions. For providing and letting us use the laboratory equipment and materials.

To our family and friends. For being there throughout this journey.
